
Implementation of a copula-based classifier

1 Description

Classifiers based on probabilistic graphical models (e.g. those based on Gaussian and Bayesian networks) are extensively applied in many areas. Recently, several methods based on Copulas have been proposed in this domain [1, 2, 3, 4, 5, 6, 7, 8]. Copulas provide a flexible tool to build multivariate distributions from marginals which are modeled by different distributions, and a function (the copula) that links these marginals. Classifiers based on copulas can be especially suited to deal with problems with a continuous representation in which there are intricate relationships among the problem variables.

2 Objectives

The goal of the project is to implement a copula-based classifier in Python. The student should:

- 1) Select one of the copula-based models proposed in the literature, or propose a new one, and implement it.
- 2) Identify which datasets are relevant for evaluating the classifier.
- 3) Validate the implementation using the datasets.

As in other projects, a report should describe the characteristics of the design, implementation, and results. A Jupyter notebook should include calls to the implemented function that illustrate the way it works.

3 Suggestions

- The copulalib Python library provides implementation of several relevant functions for learning copula from data <https://pypi.python.org/pypi/copulalib>.
- Also the pyvine library provides more sophisticated functions for learning and sampling vine copulas <https://pypi.python.org/pypi/pyvine/0.5.0>.
- One straightforward approach to build classifiers with copulas is using a Gaussian Naive Bayes approach using copulas instead of gaussian models. See <https://machinelearningmastery.com/naive-bayes-classifier-from-scratch-python/> for an implementation of Naive Bayes from scratch.
- Alternatively, any of the classifiers proposed in the literature could be implemented [1, 3, 4, 5, 6, 7, 8].
